

Random Walk Probability Script

May 16, 2022

```
[5]: import math
```

Let $\{S_n\} = \sum_{i=1}^n X_i$ where $\{X_i\}$ are iid random variables with distribution $\mathbf{P}(X_i = 1) = \mathbf{P}(X_i = -1) = \frac{1}{2}$.

Calculate $\mathbf{P}(\frac{S_{35}}{\sqrt{50}} \geq 1)$:

Note that $\mathbf{P}(\frac{S_{35}}{\sqrt{50}} \geq 1) \equiv \mathbf{P}(S_{35} \geq \sqrt{50})$ $\sqrt{50} \approx 7.07$, but this random walk can only take on integer values, as each increment is either -1 or 1. This tells us $\mathbf{P}(S_{35} \geq \sqrt{50}) = \mathbf{P}(S_{35} \geq 7.07) = \mathbf{P}(S_{35} \geq 8)$. At time index 35, the maximum value the random walk could attain would be 35 (i.e. if $\forall i \in \{1, 2, \dots, 35\}, X_i = 1, S_{35} = 35$). In addition, note that $\mathbf{P}(S_n = x) > 0 \iff n \geq x, \frac{1}{2}(n+x) \in \mathbb{Z}$, e.g. the probability that $S_2 = 3$ is zero because it's not possible to reach the value 3 in 2 time instants, and similarly the probability that $S_2 = 1$ is 0, as the possible values at that time instant are -2, 0, and 2.

```
[10]: # Find the possible values of the random walk at time index 35 using list_
      ↪ comprehension
vals = [val for val in range(8, 36) if (35+val)%2 == 0]
vals
```

```
[10]: [9, 11, 13, 15, 17, 19, 21, 23, 25, 27, 29, 31, 33, 35]
```

So the values of x for which $\mathbf{P}(S_{35} = x) > 0$ are the odd numbers between 9 and 35, inclusive. Denote this set as \mathcal{S} . Then $\mathbf{P}(S_{35} \geq 8) = \sum_{x \in \mathcal{S}} \binom{35}{x} (\frac{1}{2})^{\frac{1}{2}(35+x)} (\frac{1}{2})^{\frac{1}{2}(35-x)}$

```
[11]: p = 0
      for x in vals:
          p += math.comb(35, x)*(1/2)**((1/2)*(35+x))*(1/2)**((1/2)*(35-x))
      p
```

```
[11]: 0.49979465117212385
```

Therefore, $\mathbf{P}(\frac{S_{35}}{\sqrt{50}} \geq 1) \approx 0.4998$.
